1 Rectangles

(a) Design an $O(n \log n)$ algorithm that finds the outline of the rectangles.

```
Function mergeRect(array)
  If sizeof(array) is 1
    Return array[0]
  midpoint = sizeof(array)/2
  first = array[:midpoint]
  second = array[midpoint:]
  Return merge(mergeRect(first), mergeRect(second))

Function merge(arrayOne, arrayTwo)
  Let Output be an empty integer array
  Let Maxarray be an array of n zeros
  For each i from 0 to sizeof(arrayOne)
    For each j from i to i+2
      Maxarray[j] = max(Maxarray[j], arrayOne[i])
    i += 2
  For each i from 0 to sizeof(arrayTwo)
    For each j from i to i+2
      Maxarray[j] = max(Maxarray[j], arrayTwo[i])
    i += 2
  For each i from 0 to sizeof(Maxarray)
    Push i to Output
    Push Maxarray[i] to Output
    While Maxarray[i] == Maxarray[i+1]
      i += 1
  Return Output

Let I be the array of rectangle arrays
Sort array I by the first element of each rectangle array in ascending
Return mergeRect(I)
```

(b) Design an O(n) algorithm that, given an outline, finds a rectangle of maximal area that fits within the outline. Implement your algorithm with a single left-to-right scan through the outline data.

```
Let O be the array representing the outline
Let S, i be 0
While O[i+2] is not null
   S += (O[i+2] - O[i]) / O[i+1]
   i += 2
Return S
```

2   Interview Questions

(a) You are given a 3-pint container and a 5-pint container, and as much water as you want. Specify a sequence of filling and emptying steps that leave the containers holding exactly 7 pints of water.

The first step is to fill up the the 5-pint container and empty as much as possible into the 2-pint container. This leaves you with 3 pints and 2 pints in the two containers. The next step is to empty the full 3-pint container and pour the 2 pints from the 5-pint container into the 3-pint container. Finally, you fill the empty 5-pint container, leaving us with 2 pints in the 3-pint container and 5 pints in the 5-pint container for a total of 7 pints of water

(b) There are many problems like the one above; it is from the 1916 Stanford-Binet IQ test. A common interview question uses 3, 5, 4. Design an algorithm that, given three small integers like these as input, finds a sequence with the minimum number of steps.

```
Let a, b be the container sizes
Let z be the target
Let G be a directed graph consisting of one vertex (0, 0)
For each vertex in G
   Create an edge from (V1, V2) to (V1, V2 + V1 mod b) if not explored
   Create an edge from (V1, V2) to (V1, b) if not explored
   Create an edge from (V1, V2) to (V1, 0) if not explored
   Create an edge from (V1, V2) to (V1 + V2 mod a, V2) if not explored
   Create an edge from (V1, V2) to (a, V2) if not explored
   Create an edge from (V1, V2) to (0, V2) if not explored
   Mark (V1, V2) as explored
Let T be a Dijkstra's shortest path tree for G from (0, 0)
Use DFS on T until first coordinate + second coordinate is z
Return the stack used for DFS
```

(c) You are given an array A of n integers, and another integer z, and you want to determine whether the array contains two elements a and b such that $a + b = z$.

i. Give an algorithm that uses a min-heap and a max-heap to determine this in time $O(n \log n)$.

```
Let A be the array of integers
Let Min be a min-heap
Let Max be a max-heap
For each i from 0 to n-1
  Min.Insert(A[i])
  Max.Insert(A[i])

While FindMin(Min) < FindMax(Max)
  Sum = FindMin(Min) + FindMax(Max)
  If Sum > z
    ExtractMin(Min)
  Else if Sum < z
    ExtractMax(Max)
  Else
    Return true
Return false
```

ii. Give an algorithm that runs in time $O(n)$, assuming that A is given to you in sorted order.

```
Let A be the array of integers
Let i be 0
Let j be n-1
While i < j
  Sum = A[i] + A[j]
  If Sum > z
    j -= 1
  Else if Sum < z
    i += 1
  Else
    Return true
Return false
```

(d) You are given an array A of n integers (possibly negative) and you want to determine whether the array contains three elements a, b, and c such that $a + b + c = 0$. Give an algorithm that solves this problem in $O(n^2)$ time.

```
Let A be the array of integers
Use merge-sort to sort in ascending order
For i from 0 to n-1
  j = i+1
  k = n-1
  While j < k
    Sum = A[i] + A[j] + A[k]
```

```
        If  Sum  >  0
            k  −=  1
        Else  if  Sum  <  0
            j  +=  1
        Else
            Return  true
    Return  false
```

(e) You are given an array of size n containing every number in $0, 1, 2, ..., n$ except for one. Give an algorithm to find the missing number in time $O(n)$, using only 1 memory cell that has $\lceil 2 \log_2 n \rceil$ bits. (For example, when $n = 50000$, the cell has 32 bits, and can represent numbers from 0 to $2^{32} - 1$.)

```
    Let  I  be  the  input  array
    Let  CELL  be  the  memory  cell
    CELL  =  0
    For  each  i  from  1  to  n−1
        CELL  =  CELL  XOR  I [ i ]
    For  each  j  from  0  to  n−1
        CELL  =  CELL  XOR  j
    Return  CELL
```

3   Optimal Submatrix

(a) Find a maximal positive rectangular submatrix - i.e., a submatrix containing only positive values that has the most elements.

```
    Function  maximumPositiveMatrix ( Matrix )
        Let  MostPositive  =  0
        For  each  Left  from  0  to  columns ( Matrix )
            Let  Temp  be  an  integer  array  with  rows ( Matrix )  zeroes
            For  each  Right  from  Let  to  columns ( Matrix )
                For  each  i  from  0  to  rows ( Matrix )
                    Temp [ i ]  +=  Matrix [ i ] [ Right ]
                Let  NumPositive  =  maximumPositiveArray (Temp ,  MaxStart ,  MaxTail )
                If  NumPositive  >  MostPositive
                    MostPositive  =  NumPositive
                    MaxRowStart  =  Left ;
                    MaxRowTail  =  Right ;
                    MaxColStart  =  maxStartForRij ;
                    MaxColTail  =  maxTailForRij ;

        Return  Matrix  with  corners  MaxRowStart ,  MaxRowTail ,
            MaxColStart ,  MaxColTail
```

```
Function maximumPositiveArray(Array, byref(Start), byref(End))
   Let MostPositive = 0
   Let NumPositive = 0
   Let Start = 0
   Let End = -1
   Let Index = 0

   For each i from 0 to sizeof(Array)
      NumPositive = max(0, NumPositive + Array[x])
      MostPostive = max(MaxPositive, NumPositive)
      If MostPostive = NumPositive
         End = i
      Else
         Start = End + 1

   Return MostPositive
```

Note: rows() is the number of rows of a matrix and columns() is the number of columns of a matrix.

(b) Find a maximum sum rectangular submatrix - i.e., a submatrix whose elements have maximal sum. (Hint: This is a generalization of the 'maxsum' problem discussed at the start of this course.).

```
Function maximumSumMatrix(Matrix)
   Let MaxSum = 0
   For each Left from 0 to columns(Matrix)
      Let Temp be an integer array with rows(Matrix) zeroes
      For each Right from Let to columns(Matrix)
         For each i from 0 to rows(Matrix)
            Temp[i] += Matrix[i][Right]
         Let Sum = maximumSumArray(Temp, MaxStart, MaxTail)
         If Sum > MaxSum
            MaxSum = Sum
            MaxRowStart = Left;
            MaxRowTail = Right;
            MaxColStart = maxStartForRij;
            MaxColTail = maxTailForRij;

   Return Matrix with corners MaxRowStart, MaxRowTail,
      MaxColStart, MaxColTail
```

Note: maximumSumArray() is Kadane's Algorithm (that returns the maxsum and updates seconds and third parameters to indicate the location of the maximum subarray), rows() is the number of rows of a matrix, and columns() is the number of columns of a matrix.

4 Going Beyond the Master Theorem

(a) The recurrence can be solved via a recursion tree as follows. First we can rewire n as $n = 2^{\log n}$. With each recursive call downward, the square root will be taken. With some arbitrary z iterations of the recursion, the z-th root of n is taken as follows: $n^{1/2^k} = 2^{\log n/2^k}$. If we terminate when this expression is less than two, we logically reach $2^{\log n/2^k} = 2$, which can be rewritten as $\log n/2^k = 1$ by taken the log of both sides. This can further be simplified to $\log n = 2^k$, which after taking the log of both sides again reduces to $\log\log n = k$. With each recursion tree step doing n work, the total is $O(n\log\log n)$ which is exactly the big-O expected.

(b) $T(n) = T(2^p)$

p	$T(2^p)$	Value
0	$T(1) = 1$	1
1	$T(2) = 8$	8
2	$T(4) = 3*8 + 4*1 + 3*4 = 40$	40
3	$T(8) = 3*40 + 4*8 + 3*8 = 176$	176
4	$T(16) = 3*176 + 4*40 + 3*16 = 736$	736
5	$T(32) = 3*736 + 4*176 + 3*32 = 3008$	3008

Therefore, $T(2^p) = 2^p(3 * 2^p - 2)$. Furthermore, the integer k for which $T(n) = \Theta(n^k)$ is $k = 0$.

(c) First, it can be shown that $T(n)$ is equal to the sum $\sum_{k=1}^{n} \frac{1}{2k-1}$ simply through iteration:

$T(n) = T(n-1) + \frac{1}{2n-1}$
$T(n) = T(n-2) + \frac{1}{2n-3} + \frac{1}{2n-1}$
$T(n) = T(n-3) + \frac{1}{2n-5} + \frac{1}{2n-3} + \frac{1}{2n-1}$
$T(n) = \frac{1}{2n-1} + \frac{1}{2n-3} + \frac{1}{2n-5} + ...$
$T(n) = \sum_{k=1}^{n} \frac{1}{2k-1}$

Next, the sum can be expressed as the difference of two sums as follows: $\sum_{k=1}^{n} \frac{1}{2k-1} = \sum_{p=1}^{2n-1} \frac{1}{p} - (...)$. The first part is simply the harmonic series, which via calculus yields a result of $\log n$ for a series from 1 to n. However, given a series to $2n-1$, the solution becomes $\log\sqrt{n}$. The second part takes $O(1)$ constant time, resulting in a solution of $\log\sqrt{n} + O(1)$, where log is the natural logarithm.

(d) We begin with the following derivative, $\sum_{k=1}^{n} kc^{k-1} = \frac{d}{dc}\sum_{k=1}^{n} c^k$. From this, we can simply expand the known exponential sum as $\frac{d}{dc}\sum_{k=1}^{n} c^k = \frac{d}{dc}\left(\frac{c(c^n-1)}{c-1}\right)$, which further yields (via derivation) $\frac{nc^{n+1}-(n+1)c^n+1}{c-1^2}$. Resulting in the answer we expected of $\sum_{k=1}^{n} kc^{k-1} = \frac{nc^{n+1}-(n+1)c^n+1}{c-1^2}$.
